

Diary form assignment

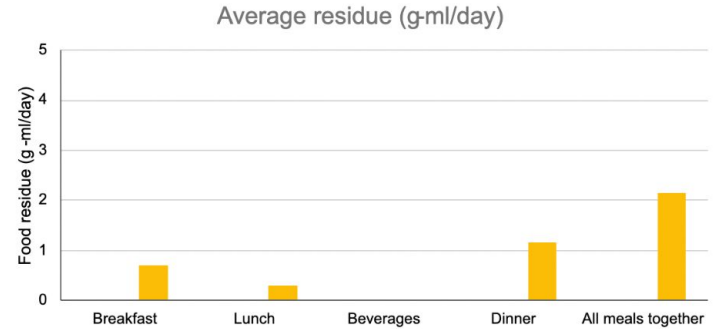

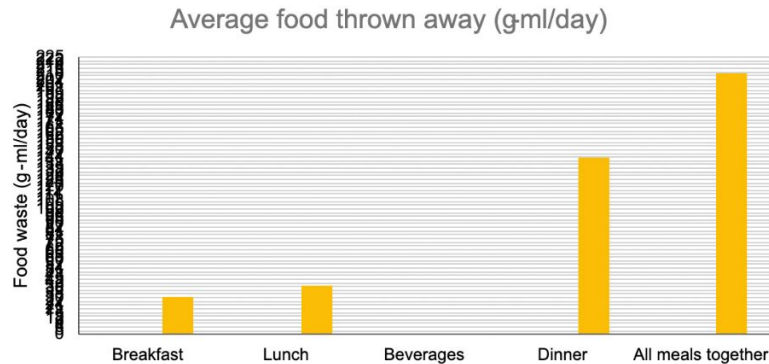

Graphs discussion

The dinner shows that it had the most residues as all the vegetables I use are packaged in a plastic bags. Butter is also double packaged, with a lid and aluminium foil. The white wine can also be a possibility of a high residue because the liquid ingredients might have the highest residues, since it is packaged in a glass bottle to make it unable to be pressured easily, which increases the product residues.

The graph shows that the way packaging is approached doesn't necessarily mean that it has a direct relationship with how much waste is consumed. The highest packaging waste was on the dinner which was approximately 74 grams/day. The whole meals together added up to be 96 grams/day. Therefore, the breakfast and lunch packaging consumption is the least if it was compared to dinner. Hence, the meals with the most ingredients complications, means it consumes more packaging. The second graph shows that dinner is around 100ml/g per day (residue/thrownaway), and all meals together are more than 100ml/grams. And this puts an eye on another observation. The problem in the usage (portioning) is a more influencing problem than the packaging problem itself.

Butter showed the least perceived sustainability score (becel proactiv) as it is made of plastic with multiple layers (with extra foil with it). The sustainability cues was present in almost all of the products, there were some products that had structural cues, that was translated in the way the products were packaged, like the plastic bags. They were very malleable, and they could be easily squeezed which reflected a positive impression to the buyer. the visual cues were represented in the green colour in some of the products, such as the eggs, butter and the olive oil plastic bottle. there were also leaves figures that showed the impression of the eco-friendly products. Verbal cues in the avocado packaging had “duurzaam” and in the eggs packaging had “bio-based”. This has affected the perceived sustainability score.

Greenwashing was very noticeable. As i found it connected with the verbal cues. The phrases (eco, green) did affect my action while purchasing them, it also gives an excuse for the price difference between the other brands

Buy, use and discard decisions

The decisions were made based on the convenience mediation- like spinach, carrots and zucchini, they were in plastic pillow bags. The salmon was in stretch films, which shows that the packages that were easy to open was something that i definitely considered while buying the product. The freshness also showed the impression it gave automatically. The packaging was transparent which gives an impression that the product-vegetables were fresh and clean. The closed bottles like wine and olive oil showed the good storage. The extraction difficulty has significantly affected my choice, since the highest residues were salmon, pastrami due to the way they were packaged.

Packaging with a perceived low sustainability score

The packaging structure:

The plastic packaging had a box, lead, and a foil cover. It is unable to be re-shaped which makes it hard to get out another layer from the product residue. Moreover, the fat residues can lead to infections and this reduces its potential to part it or wash it.

It does not show a lot of sustainability cues in the design of the packaging. It does not reflect the importance of the health benefits that the product gives.

Deep dive into the selected packaging

The packaging of Becel ProActiv was perceived as low in sustainability due to its multi-component rigid plastic structure, residue-prone geometry, and predominantly health-focused communication. These features reduced extraction efficiency, complicated disposal, and provided weak visual and verbal cues of circularity, leading to a lower perceived environmental performance compared to glass
